Project Description

Preparing for a project

We used Git and GitHub that helped us as members of the project to observe what each one of us did and the notes that explain why he did what he did.

Description of the data

When we skim through our data, we find that it's a grocery store's data. The data contains

- items sold
- count (Number of items in a single entry)
- Total price of the item entry
- Customer's name
- Customer's age
- City
- Type of Payment (Cash or Credit)

Items are types of food, vegetables, fruits, . . . , etc. Customers are from different cities and they have different ages. There are two ways to pay cash or credit. The number of transactions in this data is 9863.

Input of the program

- The path of data
- The number of clusters to used in the k-means algorithm
- The Minimum Support and minimum confidence to be used in the Apriori Algorithm

Output of the Program

- Plots :
 - Comparison between cash and credit total spending, Output from this process is plot that explain
 - * Distribution of Cash and Credit type of payment
 - * Comparing cash and credit total
 - Compare each age and sum of total spending
 - * bar Plot that Compares age and the total spending
 - Comparing the cities' total spending
 - * Bar Plot that compares cities' total spending and is displayed in descending order
 - Distribution of Total spending
 - * Box plot that highlight the Five numbers summary

- K-means :
 - The number of Cluster will be take from the user.
 - A table that contains customers, their age, total spending and the number of the cluster
- Apriori Algorithm
 - Generating Strong association rules displayed in a table form
 - * If there is no association rules after implementing the algorithm display a message containing an error

Getting and preparing the data set

The first thing we are going to do is importing the libraries we are going to use, and then import the data into a data frame. The second thing is that we will prepare data for k-means and apriori algorithms by

- Creating a data frame containing the customers, their ages, and total spending, and then grouping it by the customers
- We make the data frame suitable for k-means.
 - By sub-setting the data frame created using only the age and total columns
- We make the data suitable for apriori's algorithm by
 - Splitting the transactions entries into separate items and transforming it into a transactions object

importing the library we are going to use

```
library(dplyr)
library(ggplot2)
library(forcats)
library(arules)
library(hrbrthemes)
```

Reading the data and checking the first 10 rows of it

```
dataPath <- readline("Enter the path to the data set : ")
grc <- as_tibble(read.csv(dataPath,stringsAsFactors = FALSE))
grc <- select(grc, -rnd)
# displaying first 10 rows of our data
print(grc,n = 10, width = 80)
```

```
## # A tibble: 9,835 x 7
##   items                                count total customer  age city  paymentType
##   <chr>                                <int> <int> <chr>    <int> <chr>    <chr>
## 1 citrus fruit,semi-finished bre~    4  1612 Maged      60 Hurgh~ Cash
## 2 tropical fruit,yogurt,coffee      3   509 Eman       23 Aswan  Cash
## 3 whole milk                          1  2084 Rania       37 Dakah~ Cash
## 4 pip fruit,yogurt,cream cheese ~    4   788 Rania       37 Dakah~ Cash
## 5 other vegetables,whole milk,co~    4  1182 Magdy      36 Sohag  Cash
## 6 whole milk,butter,yogurt,rice,~    5  1771 Ahmed      30 Giza   Credit
## 7 rolls/buns                          1  2196 Huda       39 Gharb~ Cash
## 8 other vegetables,UHT-milk,roll~    5  1657 Walaa      29 Cairo  Cash
## 9 pot plants                          1  2373 Mohamed     25 Alexa~ Credit
## 10 whole milk,cereals                 2   343 Shimaa    55 Port ~ Cash
## # ... with 9,825 more rows
```

Preparing the data for k-means and apriori algorithms

```
# creating a data framing containing customers, their ages and total spending
grc_customers <- grc %>%
  select(customer,age,total) %>%
  group_by(customer)%>%
  mutate(total = sum(total))%>%
  unique()
# making the data frame suitable for k-means
grc_kmeans <- data.frame(grc_customers[,2:3],row.names = grc_customers$customer)

# splitting the items to be suitable for apriori algorithms
tdata <- strsplit(as.vector(grc$items), ',')
tdata <- transactions(tdata)
```

Visualizing our Data

Comparison between cash and credit total spending

```
boxplot_cashCredit <- ggplot(
  grc,
  aes(x = paymentType, y = total, fill = paymentType)) +
  stat_boxplot(geom = "errorbar", width = .2) +
  geom_boxplot(width = .2,
              outlier.color = "orange",
              outlier.size = 2)+
  theme_ipsum_rc() +
  xlab("Payment Type") +
  ylab("Total") +
  theme(
    plot.title = element_text(size=16)) +
  ggtitle("Distribution of Cash and Credit type of payment")
barplot_cashCredit <- ggplot(grc,
                             aes(x = paymentType,
                                y = total,
                                fill = paymentType)) +
  geom_col(width = .3) +
  scale_y_continuous(n.breaks = 12) +
  theme_ipsum() +
  theme(
    plot.title = element_text(size = 16)) +
  ggtitle("Comparing cash and credit total")

print(boxplot_cashCredit)
print(barplot_cashCredit)
```

Observations

After brief moments of seeing the figures, we find that the distribution of cash and credit types of payment is nearly identical, but the amount paid in cash is greater than the amount paid in credit.

Compare each age and sum of total spending.

Before visualizing

let's create a contingency table using the data prepared and look at number of individuals in each age group.

```
table(grc_customers$age)
```

```
##
## 22 23 25 29 30 35 36 37 39 50 55 60
##  2  1  1  1  1  1  1  2  1  1  2  1
```

It becomes clear that there are more people aged (22,37 and 55) than the other age groups

```
grc_age <- select(grc,age,total)
grc_age <- grc_age %>%
  group_by(age) %>%
  summarise(totalSpending = sum(total))
grc_age <- mutate(grc_age,age = fct_reorder(as.factor(age),totalSpending))
barPlotAgeSum<-ggplot(
  grc_age,
  aes(x = age, y = totalSpending)) +
  geom_col() +
  coord_flip() +
  theme_ipsum() +
  theme(
    plot.title = element_text(size=16),
    legend.position = "none")+
  ggtitle("Comparing age and the total spending using bar Plot")

print(barPlotAgeSum)
```

Comparing age and the total spending using bar Plot

Observations

Since there are more customers aged (22, 37 and 55), it makes sense that the total spending of these age groups is higher than the rest.

Comparing the cities' total spending

###Cleaning the data in order to be prepared for data visualization

```
C_Vs_To <-grc %>%
  select(city,total) %>%
  group_by(city) %>%
  summarise(totalspending = sum(total))
C_Vs_To <- mutate(C_Vs_To, city = fct_reorder(as.factor(city),totalspending))
print(C_Vs_To)
```

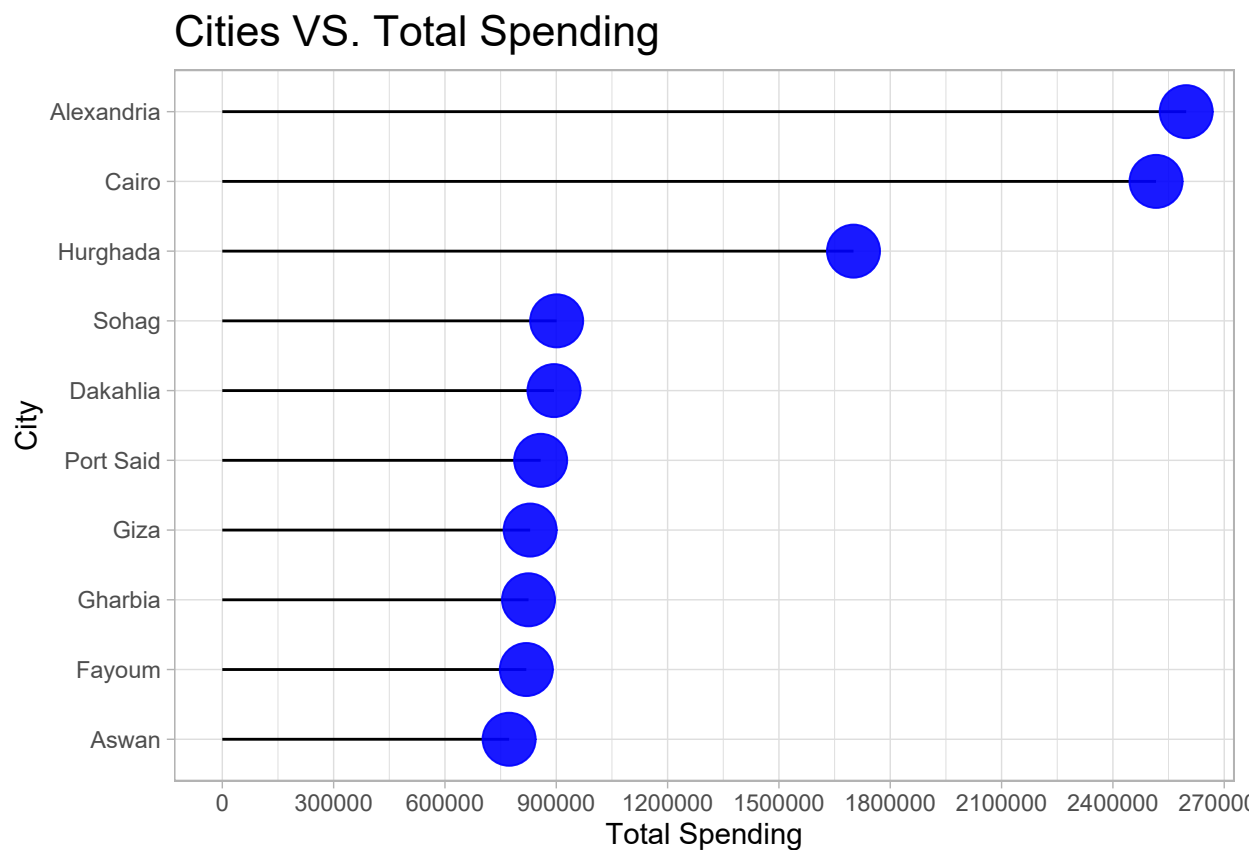

```
## # A tibble: 10 x 2
##   city      totalspending
##   <fct>         <int>
## 1 Alexandria    2597481
## 2 Aswan         772871
## 3 Cairo         2516267
## 4 Dakahlia      893789
## 5 Fayoum        819231
## 6 Gharbia       825147
## 7 Giza          829587
## 8 Hurghada     1700940
```

```
## 9 Port Said      857901
## 10 Sohag         901010
```

###Visualizing

```
CityandTotalspending<- ggplot(C_Vs_To,aes(city,totalspending)) +
  geom_segment( aes(xend=city,y = 0,yend=totalspending)) +
  scale_y_continuous(n.breaks = 10) +
  geom_point( color="blue", size=9, alpha=.9) +
  theme_light() +
  xlab("City") +
  ylab("Total Spending") +
  coord_flip() +
  theme(
    plot.title = element_text(size=16))+
  ggtitle("Cities VS. Total Spending")

print(CityandTotalspending)
```

Observations

After we doing the data visualization on cities and their total spending, We will find that Alexandria and Cairo are the highest cities in spending, Aswan and Fayoum are the smallest in spending.

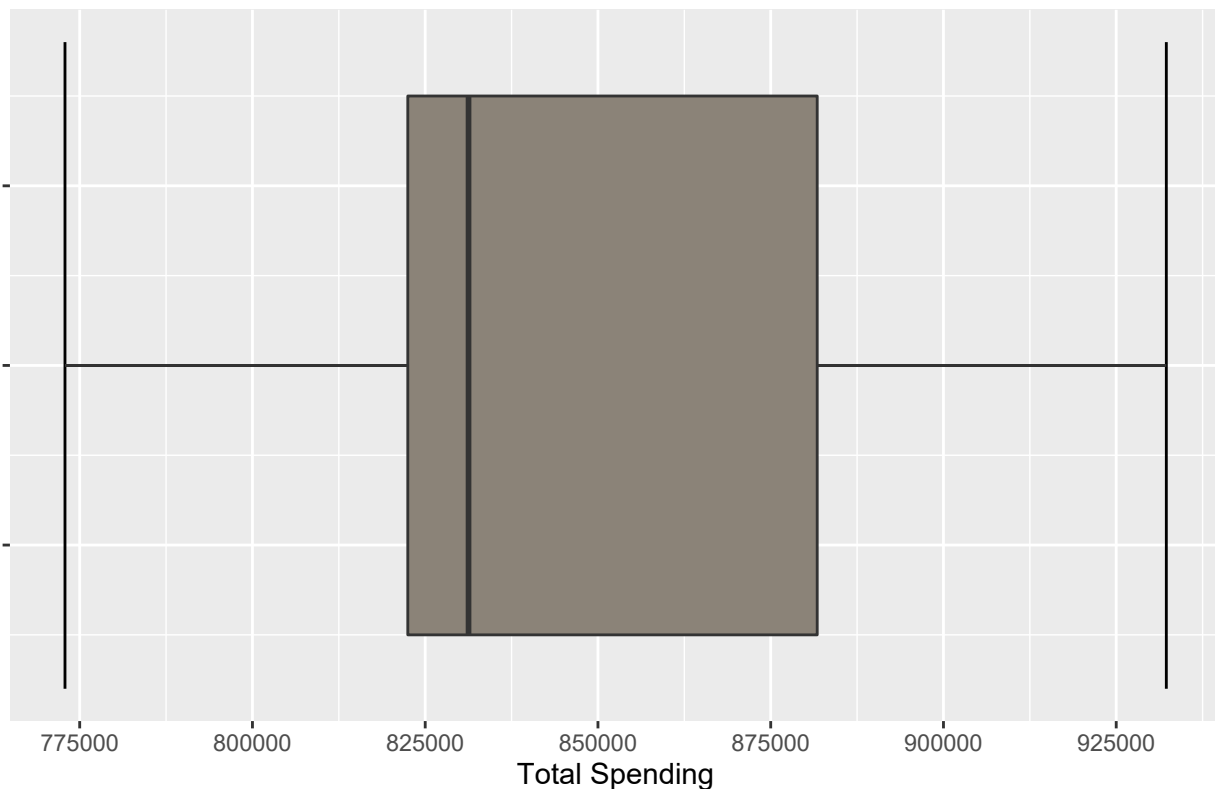

Distribution of Total spending

```
## Display the distribution of total spending.
Distribution_of_total_spending<-ggplot(grc_customers,aes(total)) +
  stat_boxplot(geom = "errorbar",width = .9) +
  geom_boxplot(fill = "antiquewhite4",) +
  scale_x_continuous(n.breaks = 8) +
  theme_grey() +
  theme(
    plot.title = element_text(size=16),
    axis.text.y = element_blank()) +
  xlab("Total Spending") +
  ggtitle("Distribution of Total spending")
summary(grc_customers)
```

```
##      customer      age      total
## Length:15      Min.   :22.0  Min.   :772871
## Class :character 1st Qu.:27.0  1st Qu.:822482
## Mode  :character Median :36.0  Median :831272
##                               Mean  :37.0  Mean  :847615
##                               3rd Qu.:44.5  3rd Qu.:881729
##                               Max.   :60.0  Max.   :932250
```

```
print(Distribution_of_total_spending)
```

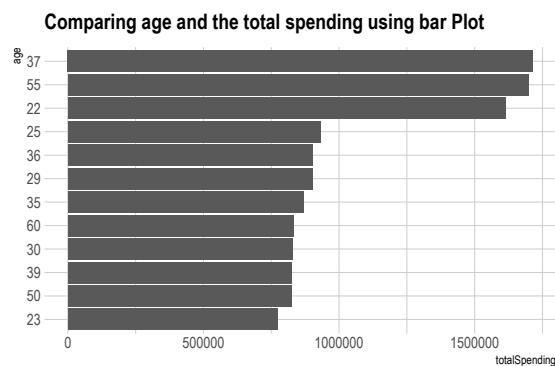

Distribution of Total spending

Observations

We will find that the total spending are between 772871 and 932250 and most of customers spend between 822482 and 881729 and their mean is 847615.

Dashboard

Distribution of Total spending

K-means

In k-means we will group the customers into (n) of clusters according to their age and their total spending and then we will put it in a table, The number of clusters will be specified by the user.

Getting the number of clusters from the user

```
No_of_clusters<-as.numeric(readline("Enter the number of clusters: "))
```

Implementation of the algorithm using the built-in function

```
Kmeans_Algorithm<-kmeans(grc_kmeans,centers = No_of_clusters)
grc_kmeans<-mutate(grc_kmeans,cluster=Kmeans_Algorithm$cluster)
print(grc_kmeans)
```

```
##      age  total cluster
## Maged   60 831272      1
## Eman    23 772871      1
## Rania   37 893789      2
## Magdy   36 901010      2
## Ahmed   30 829587      1
## Huda    39 825147      1
## Walaa   29 900797      2
## Mohamed 25 932250      2
## Shimaa  55 857901      2
## Farida  22 794570      1
## Hanan   22 819231      1
## Sayed   37 820900      1
## Adel    50 824064      1
## Sameh   35 869668      2
## Samy    55 841167      1
```

Generating the association rules

Brief explanation of Apriori algorithm for generating the rules

Apriori algorithm is an iterative approach for discovering the most frequent item sets. The frequent item sets generated by the algorithm can be used to determine association rules that highlight general trends in the data-set, it is especially useful in the analysis of super-market items in our data set

Implementing the algorithm

Reading both minimum support and minimum confidence from the user

```
min_support <- as.numeric(readline("Enter the minimum Support : "))
min_conf <- as.numeric(readline("Enter the minimum Confidence : "))
```

implementing the algorithm using the built-in function

```
apriori_rules <- apriori(
  tdata,
  parameter = list(supp = min_support, conf = min_conf, minlen = 2))
```

```
## Apriori
##
## Parameter specification:
## confidence minval  smax  arem  aval originalSupport  maxtime support minlen maxlen target  ext
##           0.5     0.1    1 none  FALSE              TRUE        5     0.01      2     10 rules TRUE
```

```
##
## Algorithmic control:
## filter tree heap memopt load sort verbose
## 0.1 TRUE TRUE FALSE TRUE 2 TRUE
##
## Absolute minimum support count: 98
##
## set item appearances ...[0 item(s)] done [0.00s].
## set transactions ...[169 item(s), 9835 transaction(s)] done [0.01s].
## sorting and recoding items ... [88 item(s)] done [0.00s].
## creating transaction tree ... done [0.00s].
## checking subsets of size 1 2 3 4 done [0.00s].
## writing ... [15 rule(s)] done [0.00s].
## creating S4 object ... done [0.00s].
```

Printing the result Taking into consideration that there might be no rules generated.

```
# Displaying at most 100 rows of the rules
if(length(size(apriori_rules)) == 0){
  print(
    paste(
      "No rules were generated when Minimum Support equals",
      min_support,
      "and Minimum confidence equals",
      min_conf))
}else{
  as_tibble(DATAFRAME(apriori_rules, separate = TRUE, setStart = "", setEnd = "")) %>%
    print(n = 100, width = 90)
}
```

```
